

Grasshopper Script

Python Script

```
5 import Rhino.Geometry as rg
6 import rhinoscriptsyntax as rs
7 import random
8
9 #=====#
10 # 0. These are parameters that weight the different behaviours. Try adjusting them.
11
12 #sight_radius = 8 # how far the boid "sees"
13 #max_speed = .5
14 #align_factor = 1
15 #separate_factor = 1.7
16 #cohere_factor = 1.5
17 #boundary_factor = 1
18 #z_factor = 1
19
20 #=====#
21 # 1. Define the boid Agent class, which contains the methods that make up its movement behaviours
22
23 class Agent():
24     def __init__(self, init_position, init_velocity):
25         self.position = init_position
26         self.velocity = init_velocity
27         self.trail = [init_position]
28
29     def move(self):
30         self.position = self.position + self.velocity
31         self.trail.append(self.position)
32
33     def flock(self, all_boids):
34         other_boids = all_boids[:]
35         other_boids.remove(self)
36
37         # this defines the self variables of each instance of the Agent class
38         # the current position in space of the boid, as (x,y,z)
39         # a vector showing direction and amount of movement towards next position
40         # list of all positions of the boid, starting with the initial
41
42         # updates boid position based on heading
43         # set new position into the self variable
44         # add new position into the trail list
45
46         # flocking movement is made up of three behaviours: alignment, separation, and cohesion
47         # we will call each of those methods here to calculate the velocity (heading) of the boid Agent
48         # the [:] is Python specific, to make sure the two variables' values aren't secretly linked
49         # take this boid Agent out of the list
```
